Abstract (Basic): US 5448242 A

The system protects a transponder or tag (14) from being enabled or awakened by spurious RF energy. A modulation detector (64) is provided which detects a modulation signal that is superimposed upon an RF modulation from an interrogator (12). Pref the superimposed modulation is of a low frequency, below those typically existing as Electro-Magnetic Interference (EMI), such that the transponder (14) is less likely to be erroneously activated by an unintended RF signal.

Upon reception of an RF interrogation having the correct modulation superimposed on it, the modulation detector (64) is operated to awaken other circuitry within the transponder (14) such that the transponder (14) is then operable to communicate with the interrogator (12).

USE/ADVANTAGE - Radio frequency identification of transponder by interrogator in automatic vehicle identification type of recognition system.
